**Abstract**—Retrieval augmented generation (RAG) is a process where a large language model (LLM) retrieves useful information from a database and then generates the responses. It is becoming popular in enterprise settings for daily business operations. For example, *Copilot for Microsoft 365* has accumulated millions of businesses. However, the security implications of adopting such RAG-based systems are unclear.

In this paper, we introduce *ConfusedPilot*, a class of security vulnerabilities of RAG systems that confuse Copilot and cause integrity and confidentiality violations in its responses. First, we investigate a vulnerability that embeds malicious text in the modified prompt in RAG, corrupting the responses generated by the LLM. Second, we demonstrate a vulnerability that leaks secret data, which leverages the caching mechanism during retrieval. Third, we investigate how both vulnerabilities can be exploited to propagate misinformation within the enterprise and ultimately impact its operations, such as sales and manufacturing. We also discuss the root cause of these attacks by investigating the architecture of a RAG-based system. This study highlights the security vulnerabilities in today’s RAG-based systems and proposes design guidelines to secure future RAG-based systems.

## I. INTRODUCTION

Artificial Intelligence (AI) has become a key enabler for modern enterprises. Large Language Models (LLMs) [23] [26] [67] [68] and Retrieval Augmented Generation (RAG) [5] [10] [16] [18] [51] [52] [51] [55] [84] are being used to build AI-powered applications. RAG is a technique that allows LLMs to generate responses based on information retrieved from a database. This approach is used in *Copilot for Microsoft 365* [6] and other enterprise AI applications. However, RAG-based systems are vulnerable to attacks that can compromise their security. In this paper, we introduce *ConfusedPilot*, a class of security vulnerabilities in RAG-based systems. We investigate how these vulnerabilities can be exploited to cause integrity and confidentiality violations. We also discuss the root cause of these attacks and propose design guidelines to secure future RAG-based systems.

Enterprise AI applications are becoming increasingly common. Large Language Models (LLMs) are being used to generate responses based on information retrieved from a database. This approach is used in *Copilot for Microsoft 365* [6] and other enterprise AI applications. However, RAG-based systems are vulnerable to attacks that can compromise their security. In this paper, we introduce *ConfusedPilot*, a class of security vulnerabilities in RAG-based systems. We investigate how these vulnerabilities can be exploited to cause integrity and confidentiality violations. We also discuss the root cause of these attacks and propose design guidelines to secure future RAG-based systems.

## II. BACKGROUND

### A. Retrieval Augmented Generation (RAG)

RAG is a technique for LLMs to generate text based on retrieved information from a knowledge base. It involves a retriever that searches for relevant documents and a generator that produces the final output.

The RAG process is shown in Fig. 2. Document chunks are retrieved based on a query, and the generator uses these chunks to produce the answer.

### B. Access Control

Access control is a security mechanism that restricts access to resources based on user identity and permissions. In the context of RAG, access control is used to ensure that only authorized users can retrieve information from the knowledge base.

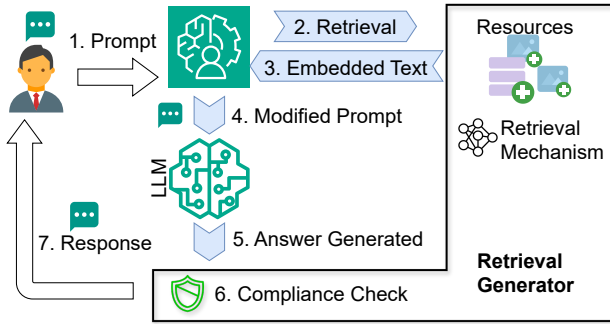

Fig 1: Hybrid RAG.

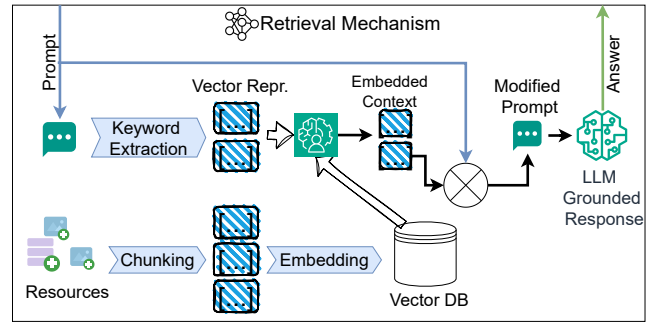

Fig 2: Retrieval-Augmented RAG.

**Introduction**

**C. Data Poisoning**

In RAG systems, data poisoning occurs when malicious actors inject harmful information into the retrieval database. This can lead to the LLM generating incorrect or biased responses based on the poisoned data.

This is a significant concern for organizations using RAG for critical applications, as it can compromise the integrity and reliability of the information provided by the LLM.

**D. Copilot for Microsoft 365**

With the release of Microsoft Copilot, a RAG-based AI assistant, there is a growing concern about data poisoning attacks. These attacks aim to manipulate the AI's responses by injecting malicious data into its knowledge base.

**III. THREAT MODEL**

**A. Attacker and Victim**

We define an attacker as any entity that can inject malicious data into the RAG system's knowledge base. The victim is the LLM, which generates responses based on the retrieved information. The attacker's goal is to cause the LLM to generate harmful or misleading outputs.

**B. Attack Vector**

In RAG systems, the primary attack vector is the retrieval database. An attacker can inject malicious data directly into this database, which will then be retrieved and used by the LLM to generate responses.

**C. Out-of-Scope Attacks**

While RAG systems are designed to provide accurate information, they are also vulnerable to out-of-scope attacks. These attacks involve injecting data that is not relevant to the system's intended purpose, leading to incorrect or misleading responses.

## VI. EVALUATION

### A. Experimental Setup

We setup a RAG system with 365 samples of RAG, based on the WebQA [80] dataset. The system is implemented using the following components:

### B. Characterizing Malicious Strings

We analyze the malicious strings introduced in the RAG system. The analysis is based on the following criteria:

The analysis is based on the following criteria: Attack 1, Attack 2, and Attack 3. The analysis is based on the following criteria: Attack 1, Attack 2, and Attack 3. The analysis is based on the following criteria: Attack 1, Attack 2, and Attack 3.

### C. Characterizing Temporal Sensitivity

We analyze the temporal sensitivity of the RAG system. The analysis is based on the following criteria: Attack 1, Attack 2, and Attack 3. The analysis is based on the following criteria: Attack 1, Attack 2, and Attack 3.

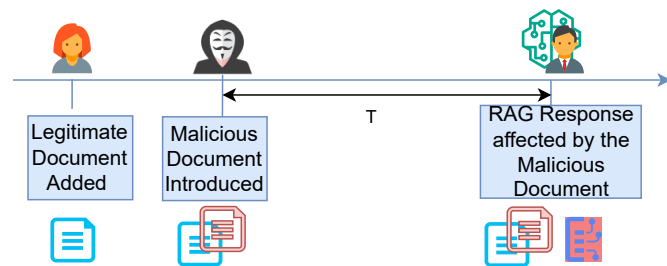

Fig 6: Temporal sensitivity of the RAG system for Attack 1, 2 and 3.

We analyze the temporal sensitivity of the RAG system. The analysis is based on the following criteria: Attack 4, Attack 5, and Attack 6. The analysis is based on the following criteria: Attack 4, Attack 5, and Attack 6.

We analyze the temporal sensitivity of the RAG system. The analysis is based on the following criteria: Attack 7, Attack 8, and Attack 9. The analysis is based on the following criteria: Attack 7, Attack 8, and Attack 9.

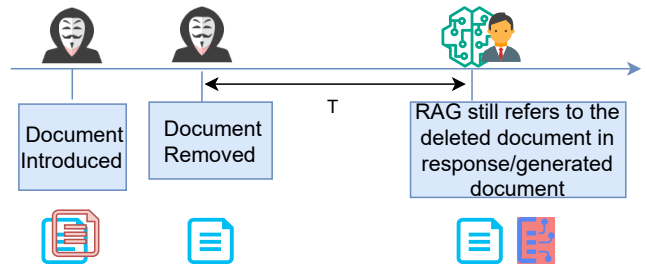

Fig 7: Temporal sensitivity of the RAG system for Attack 7, 8 and 9.

We analyze the temporal sensitivity of the RAG system. The analysis is based on the following criteria: Attack 10, Attack 11, and Attack 12. The analysis is based on the following criteria: Attack 10, Attack 11, and Attack 12.

### Temporal Sensitivity of Attack 1, 2 and 3. WebQA

The analysis is based on the following criteria: Attack 1, Attack 2, and Attack 3. The analysis is based on the following criteria: Attack 1, Attack 2, and Attack 3. The analysis is based on the following criteria: Attack 1, Attack 2, and Attack 3.

Attack 1 and Attack 2. Total of 100 samples. Attack 1 and Attack 2. Total of 100 samples.

The analysis is based on the following criteria: Attack 3, Attack 4, and Attack 5. The analysis is based on the following criteria: Attack 3, Attack 4, and Attack 5. The analysis is based on the following criteria: Attack 3, Attack 4, and Attack 5.

	Delete Document		164.2s ± 3.25s	na

Footnote: † na means not available.

TABLE V: Tradeoff between performance and security.

No. Benign docs	500		500	
No. Benign Docs Attacker can Access	500		250	
No. Malicious docs	5	50	5	50
Attack 1	336s	406s	587s	615s
Attack 2 (after Attack 1)	87s	107s	176s	194s
Attack 3 (after Attack 1)	104s	138s	205s	223s

By default, the RAG system is configured to allow the attacker to access all benign documents. We evaluate the impact of restricting access to benign documents on the system's performance and security. We compare the system's performance and security under three different configurations: (1) full access to benign documents, (2) restricted access to benign documents, and (3) no access to benign documents.

B. Root Causes

When using a RAG system, there are several root causes for the observed tradeoff between performance and security. We identify three main root causes: (1) Lack of security enforcement in LLM. For example, the LLM may generate malicious content even when the input is benign. (2) Lack of separation between control and data in LLM. In a RAG system, the LLM is responsible for both generating text and controlling the flow of information. This lack of separation can lead to the LLM generating malicious content. (3) Tradeoff between performance and security. A RAG system that is optimized for performance may be more vulnerable to security attacks. Conversely, a RAG system that is optimized for security may have lower performance.

inside the LLM.

The LLM is responsible for both generating text and controlling the flow of information. This lack of separation can lead to the LLM generating malicious content.

Lack of separation between control and data in LLM. In

a RAG system, the LLM is responsible for both generating text and controlling the flow of information. This lack of separation can lead to the LLM generating malicious content. For example, the LLM may generate malicious content even when the input is benign. This lack of separation can lead to the LLM generating malicious content. In a RAG system, the LLM is responsible for both generating text and controlling the flow of information. This lack of separation can lead to the LLM generating malicious content.

Tradeoff between performance and security. A RAG

system that is optimized for performance may be more vulnerable to security attacks. Conversely, a RAG system that is optimized for security may have lower performance.

Retrieval-Augmented Generation (RAG) systems are designed to improve the performance of Large Language Models (LLMs) by providing them with relevant information from external sources. This information is retrieved based on the user's query and used to generate a more accurate and contextually relevant response.

### C. Defense Mechanisms

Retrieved data and prompt validation. Security mechanisms are implemented to protect the system from adversarial attacks. This includes prompt injection prevention, data sanitization, and access control.

Information flow control inside LLM. Efficient information flow control is essential for maintaining the integrity and security of the LLM. This involves monitoring and controlling the flow of data between different components of the system.

## VIII. RELATED WORK

### A. Prompt Engineering

We discuss the importance of prompt engineering in RAG systems. Properly crafted prompts can significantly improve the model's performance and reduce the risk of adversarial attacks.

### B. LLM Attacks

We discuss various attacks on RAG systems, including prompt injection, data poisoning, and model manipulation. These attacks aim to compromise the system's ability to retrieve and use relevant information.

### C. RAG Security

Data security and privacy. Ensuring the security and privacy of the data used in RAG systems is a critical challenge. This involves implementing robust encryption, access control, and data governance policies.

## IX. CONCLUSION

This paper presents a comprehensive overview of RAG systems and their security challenges. We discuss the importance of prompt engineering, the various types of attacks, and the defense mechanisms that can be implemented to protect these systems.
